# "Estimation of Probability of Defaults (PD) for Low Default Portfolios: An Actuarial Approach"

Nabil Iqbal & Syed Afraz Ali

January 2012

## Abstract:

Global financial crises like the one recently experienced, affected both large and small institutions. Today, when there is heightened need for enhanced risk management tools, there are entities that are unable to employ sophisticated mechanisms due to limited data availability. Moreover, from the Basel II and Basel III point of view, Internal Ratings Based Approach requires that institutions have some reliable estimates of probabilities of default for each rating grade. Taking the work of previous researches a step further, this paper intends to propose a new dynamic mechanism to the risk management industry for calculating probabilities of default (PD). Through this, we calculate the realized probability of defaults and Bayesian estimates in the initial phase and then using these estimates as inputs for the core model, we generate Implied Probability of Default (PD) through actuarial estimation tools and different probability distributions. This mechanism is specialized to work best for Low Default Portfolios (LDPs). Furthermore, scenario testing is adopted to validate the model against any model specific bias.

**Key Words:** Probability of Defaults (PDs), Realized PDs, Bayesian Estimates, Probability Distributions

# **Authors' Introduction:**

**Nabil Iqbal:** Currently working in Group Risk with Qatar National Bank (QNB), Qatar and responsible for the ALM and Basel II implementation of Algorithmics RiskWatch & Moody's RiskFrontier. Previously has worked with Soneri Bank Limited, Pakistan for more than three years as Manager, Risk Analytics & Economic Capital. Established the Risk Analytics Department, developed various models in-house for the bank and then successfully implemented SAS for the Basel II IRB Approaches preparation. Antecedently, established Risk Modeling Department in Bank Islami Pakistan while working there for a year. Started the career in 2006 with KPMG Pakistan and served the Risk Advisory Services in Data & Gap Analysis projects for the Basel II implementation. On the academic end, holds specialized degree in Actuarial Science & Risk Management.

## 1. Introduction:

Today, in this gigantic pasture of Risk Management, improved Credit Risk Management has become the need of Financial Institutions all around the world. Specifically speaking, many Financial Institutions have either moved or are about to move towards Internal Ratings Based Approach. The most important step in switching towards Internal Ratings Based Approach; whether Foundation or Advanced, is to determine Probability of Default (PD) for each risk grade. Probability of default has much significance as it is one of the core parts for better allocation of capital, better pricing, client judgment, regulatory compliance and finally better monitoring of high risky customers. Due to these significant reasons, a financial institution should be assured that the probability of default determination is sophisticated and more importantly shows the true picture of the portfolio in present as well as future scenarios.

Many Financial Institutions use long term realized probability of default for calculating capital charge but this methodology has its limitations. On the other hand, another issue which has been raised in last few years is the estimation of probability of default for Low Default Portfolios (LDPs). For LDPs, realized PDs cannot show the true behavior of defaults. Less number of defaults or less data always creates hurdle in determining the true probability of default. Despite that realized probability of defaults cannot be ignored and should be used as an input in determining the final results.

Another important property is to take into account the posterior probability of default of each grade. Knowledge of how specific grades perform within the default portfolio or alternatively the weight of default of each grade within the portfolio should also be used as an input to evaluate this behavior. Bayesian Theorem is widely used criteria to obtain the weight of default of each grade within the total number of defaults of the portfolio. This paper also uses the Bayesian estimates inputs for the model.

Subprime crisis taught financial institutions several lessons in enhanced risk management. For this practical reason we believe that every low grade portfolio should take into account the behavior of a higher grade portfolio. Big organizations having better credit ratings start to default and simultaneously, organizations having lower ratings follow suit. This paper captures this relationship between the grades through specific models and brief cases.

Taking into account all of the above features, we propose a new mechanism to obtain the probability of default for every grade. This model is very dynamic; it incorporates all the necessary aspects together and returns an implied probability of default for each grade. The theme of the model is mainly based on a mechanism called *'convolution'*. Being over a hundred years old with several applications in signal processing, optical, and engineering, statistics and actuarial sciences, practitioners must be aware of this mechanism. Also, this mechanism had been used in one of the approaches to develop Operational Value at Risk (Ops VaR) model through loss distribution. Convolution actually combines two probability distributions together to produce a new and modified distribution. We will further explain the mechanism in the following section.

Revisiting LDPs, few practitioners have in last few years developed sophisticated mechanisms for probability of default estimations. Pluto & Tasche (2005), Nicholas M.

Kiefer (2008) and few more practitioners proposed some refined tools and methodologies for the same purpose. Now, stepping forward, through this paper we propose another advance mechanism which takes into account the inputs in very different manner. The model is incorporates simple inputs from different angles but returns a single result in the form of implied Probability of Default (PD) eliminating the problem of limited number of data.

In short, Implied Probability of Default will be the terminology of our desired results. One of the probabilities used will be Bayesian estimates and the other one will be the realized probability of default of each grade (number of defaults divided by number of customers).

# 2. The Model:

This paper presents a new methodology for obtaining Probability of defaults (PD) of the rating grades which can be further used in Internal Rating Based (IRB) approach of Credit Risk in Basel II. This model specifically caters to the issue of Low Default Portfolios (LDPs) for obtaining probability of defaults<sup>1</sup>. Another specialty of the model is to incorporate the relationship between the grades. For instance, a major change in speculative grades will result in a change in the investment grades as well and vice versa. This model is suitable during times of financial crises where highly-rated institutions defaulted.

The main idea behind presenting this paper is to propose a new dynamic model which can be widely used in Credit Risk Management for obtaining Probability of Default. We are using an actuarial methodology of 'convolution' which will be the base of our whole model. Mathematically speaking, convolution is basically an operation on two functions f(x) and g(x) that returns a third function which is actually the modified version of one of the original functions. Here, we are convoluting two probability distributions which return a modified new distribution that forms the cross of those distributions. Convolution has also been used in developing Ops VaR Model but this is the first time that it is being applied for Credit Risk Management. Up till now, many practitioners have used different distributions for obtaining Probability of Default of each grade, but here, we are combining two different probability distributions to get a new modified probability distribution. The results will definitely provide better estimates and the model can be widely used in every kind of portfolio, especially in low default portfolios (LDPs).

Our model will utilize simple information from the portfolio. As discussed in the preceding section, the model only uses total number of customers and total number of defaults in each grade. One of our main concerns is to utilize the weight of default of each grade within the defaulted portfolio which will be obtained simply by applying Bayesian's Theorem. It will produce the probability of default in each grade of the next customer which will be part of the portfolio. For example if we have the following portfolio:

<sup>&</sup>lt;sup>1</sup> The use of this model is not restricted and can be applied to a variety of portfolios

Number of Obligors	Number of Defaults	
34	1	
56	1	
119	3	
257	2	
191	2	
102	6	
50	3	
34	1	
12	2	
	21	
	34 56 119 257 191 102 50 34	

Table 1.1

Now, as Bayesian Theorem says,

$$P(A|B) = \frac{P(B|A) P(A)}{P(B)}.$$

Where;

A: is percentage of Obligors in a Grade B: is an event of Default

Therefore our table will provide results for each grade in this way:

Grade	Number of Obligors	Number of Defaults	Bayesian Estimates
AAA	34	1	4.76%
AA	56	1	4.76%
А	119	3	14.29%
BBB	257	2	9.52%
BB	191	2	9.52%
В	102	6	28.57%
CCC	50	3	14.29%
CC	34	1	4.76%
С	12	2	9.52%
Sum of Defaults		21	

Table 1.2

The above derives Bayesian Estimate which provides the weights of default in each grade given the total number of defaults of the whole portfolio or simply, the probabilities of each grade given the total number of defaults in that grade. This estimate can only answer the question that given a default, what is the probability that the obligor has a particular grade.

Therefore, to make this estimate useful, we will develop a probability distribution function which will enable us to calculate the probabilities of grades with multiple defaults, given

Copyright © 2012 Nabil Iqbal & Syed Afraz Ali. No part of this publication may be reproduced, stored in a retrieval system, used in a spreadsheet, or transmitted in any form or by any means—electronic, mechanical, photocopying, recording, or otherwise—without the permission of the authors.

the total number of defaults in that grade. For example, in the above table, for grade BBB, Bayesian Estimate generates 0.0952 which shows the probability of the grade BBB if the default occurs in the portfolio or we can state that given a default in the portfolio, there is 9.52% chance that the default belongs to the grade BBB.

Going forward, one of our objective is to determine the probability if the number of defaults differ from the number of default in grade BBB. For example, in our portfolio the number of defaults in grade BBB is 2 but we want to know the probability if the number of defaults is other than 2. For this purpose the binomial distribution is the most suited distribution which will provide the desired probability at different number of defaults in a particular grade.

Considering the above example, we have a total of 21 defaults in our portfolio and we want to know the probability of every possible occurrence of default in grade BBB.

As we know, the Binomial Distribution has the Probability Mass Function (pmf):

$$P(X=k) = \binom{n}{k} p^{k} (1-p)^{n-k}$$

Where the parameters are defined as,

n = total number of defaults in the portfolio

k = number of defaults in particular grade

p = probability as estimated by Bayesian Theorem

By doing so we are able to get the results for each grade (e. g. BBB in the following table) in the form which is shown in Table 1.3.

Grade	BBB
Total Defaults	2
Bayesian	9.52%
estimate	
Table 1.3	

Hence the estimated probabilities of default of different occurrences are generated through Binomial Distribution as,

х	P ( X=x )
0	0.358942365
1	0.376889483
2	0.188444741
3	0.059674168
4	0.013426688
5	0.002282537
6	0.000304338

Copyright © 2012 Nabil Iqbal & Syed Afraz Ali. No part of this publication may be reproduced, stored in a retrieval system, used in a spreadsheet, or transmitted in any form or by any means—electronic, mechanical, photocopying, recording, or otherwise—without the permission of the authors.

7	3.26077E-05
8	2.85317E-06
9	2.06062E-07
10	1.23637E-08
11	6.18187E-10
12	2.57578E-11
13	8.91616E-13
14	2.54747E-14
15	5.94411E-16
16	1.11452E-17
17	1.639E-19
18	1.82111E-21
19	1.43772E-23
20	7.1886E-26
Table 1.4	

Similar tables for remaining grades will be illustrated later in the paper.

Up till now, we have generated probabilities of default by just using the actual and total number of defaults in the portfolio. We have not taken into account the number of customers in each grade (or the default frequencies). Next we take into account the above as well and generate a frequency distribution with Poisson distribution being the most suitable one.

Refer to the Table 1.1; we first calculate the parameter of the distribution which is lambda  $\lambda$  which will take the impact of number of obligors and defaults against them in each grade. Results are shown in Table 1.5:

Grade	Number of Obligors	Number of Defaults	Lambda 'λ'		
AAA	34	1	2.9%		
AA	56	1	1.8%		
А	119	3	2.5%		
BBB	257	2	0.8%		
BB	191	2	1.0%		
В	102	6	5.9%		
CCC	50	3	6.0%		
CC	34	1	2.9%		
С	12	2	16.7%		

### Table 1.5

Once the lambda for each grade has been estimated, we can fit the Poisson distribution, results of which will be further included in our next step, convolution.

Copyright © 2012 Nabil Iqbal & Syed Afraz Ali. No part of this publication may be reproduced, stored in a retrieval system, used in a spreadsheet, or transmitted in any form or by any means—electronic, mechanical, photocopying, recording, or otherwise—without the permission of the authors.

As we know the Probability Mass Function (pmf) of the Poisson distribution is:

$$p(x,\lambda)=rac{e^{-\lambda}\lambda^x}{x!} \hspace{0.5cm} ext{for} \hspace{0.1cm} x=0,1,2,\cdots$$

where,

 $\lambda$  = frequency of default in each grade

 $\mathbf{x}$  = number of incremental default in the specific grade

Poisson distribution will generate the probabilities of incremental default in every grade and these results will then be injected to our foundation model, convolution. In our example of grade BBB, the results are:

λ	0.0077821
n	P(N=n)
0	0.9922481
1	0.0077218
2	0.0000300
3	0.0000001
4	0.0000000
5	0.0000000
6	0.0000000
7	0.0000000

Table 1.6

The results after running convolution model provide a matrix for every grade. Here, in our example of BBB grade, the resultant matrix is being provided here under:

Similarly, matrices for each grade have been generated which provided us with the final results of the model. The values in the last column give the convoluted probabilities for BBB grade. The number of defaults was 2 in BBB in our example; hence we are interested to pick the value which has been calculated in front of number 2, i.e. 0.00025006. Be sure, this is not the probability of default for grade BBB. To obtain the final probability of default, we must calculate the convoluted probability against the original number of defaults in a specific grade and then the resulting cumulated probabilities will be the desired probabilities of default for that grade. Results are given in the table below:

Grade	PDs
AAA	1.08%
AA	1.74%
А	2.33%
BBB	2.55%
BB	2.85%
В	3.90%
CCC	5.28%
CC	6.36%
С	10.46%
Table 1.7	

#### 3. Scenarios:

In this section we intend to develop various scenarios and evaluate the model. We appraise the behavior of the model in different circumstances along with the behavior of the probability of default in a specific grade and its impact on the whole portfolio. For instance, increasing the number of customers, make the first probability distribution active, changes the realized probability of default and will then convolute with the second probability distribution providing modified probability distribution to produce the implied probability of default for each grade. On the other hand when we will change the number of defaults in any grade then the first probability distribution and second probability distribution both become active, the realized probability of default and the Bayesian estimates, both change and then convolute with each other to produce modified probability distribution. Finally, the implied probability of defaults for each grade will be produced. Let's take different scenarios and see the results.

#### **3.1.** Actual Portfolio:

Grades	No. of Customers	No. of Defaults	Realized PDs	Bayesian Estimates	Implied PDs of Actual Portfolio
AAA	34	1	2.94%	4.76%	1.08%
AA	56	1	1.79%	4.76%	1.74%
А	119	3	2.52%	14.29%	2.33%
BBB	257	2	0.78%	9.52%	2.55%
BB	191	2	1.05%	9.52%	2.85%
В	102	6	5.88%	28.57%	3.90%
CCC	50	3	6.00%	14.29%	5.28%
CC	34	1	2.94%	4.76%	6.36%
С	12	2	16.67%	9.52%	10.46%
Total	855	21			

Firstly, we gathered all the inputs and results of the actual portfolio<sup>2</sup> as tabulated below.

Table 2.1

### 3.2. Scenario 1

In our first scenario we simply study the model behavior by increasing the number of customers in the portfolio. The details of the inputs, implied probabilities of default from the actual portfolio and the implied probability of default under the given scenario are as:

Grades	No. of Customers	No. of Defaults	Realized PDs	Bayesian Estimates	Implied PDs of Actual Portfolio	Implied PDs in Current Scenario
AAA	68	1	1.47%	4.76%	1.08%	0.55%
AA	112	1	0.89%	4.76%	1.74%	0.88%
А	238	3	1.26%	14.29%	2.33%	1.18%
BBB	514	2	0.39%	9.52%	2.55%	1.29%
BB	382	2	0.52%	9.52%	2.85%	1.44%
В	204	6	2.94%	28.57%	3.90%	1.98%
CCC	100	3	3.00%	14.29%	5.28%	2.69%
CC	68	1	1.47%	4.76%	6.36%	3.24%
С	24	2	8.33%	9.52%	10.46%	5.44%
Total	1,710	21				

Table 2.2

<sup>&</sup>lt;sup>2</sup>For the purpose of comparison we show the final results from the actual portfolio under all scenarios.

Copyright © 2012 Nabil Iqbal & Syed Afraz Ali. No part of this publication may be reproduced, stored in a retrieval system, used in a spreadsheet, or transmitted in any form or by any means—electronic, mechanical, photocopying, recording, or otherwise—without the permission of the authors.

We see that the number of customers have doubled in each grade. Realized probabilities of default change and become less for each grade, Bayesian estimates are unchanged and finally the implied probabilities of default also decrease with the realized probabilities of default.

# 3.3. Scenario 2

In second scenario, we have increased the number of defaults, in fact, doubled the numbers of defaults in each grade. Table below shows the complete details:

Grades	No. of Customers	No. of Defaults	Realized PDs	Bayesian Estimates	Implied PDs of Actual Portfolio	Implied PDs in Current Scenario
AAA	34	2	5.88%	4.76%	1.08%	1.55%
AA	56	2	3.57%	4.76%	1.74%	2.51%
А	119	6	5.04%	14.29%	2.33%	3.34%
BBB	257	4	1.56%	9.52%	2.55%	3.66%
BB	191	4	2.09%	9.52%	2.85%	4.08%
В	102	12	11.76%	28.57%	3.90%	5.50%
CCC	50	6	12.00%	14.29%	5.28%	7.36%
CC	34	2	5.88%	4.76%	6.36%	8.91%
С	12	4	33.33%	9.52%	10.46%	14.00%
Total	855	42				

Table 2.3

Table 2.3 shows that as the number of defaults increase, the probabilities of default also increase. However, it is the results of Bayesian estimates that are noteworthy. If we compare the Bayesian estimates of Table 2.2 with Table 2.3 we will find no change in any grade. This is because the defaults increase with the same weightage in all the grades. Therefore, in convoluted probabilities, the process only takes effect of the increment in defaults from the realized probabilities of default, while the Bayesian estimates show the same properties in both cases.

# 3.4. Scenario 3

Under this scenario, we try to find the relationship between implied probabilities of default and all the other inputs if both the number of defaults and number of customers increase. Applying this scenario to the realized probabilities of default would not change values since the number of customers and the number of defaults are both doubled. Here are the details after running the model:

Copyright © 2012 Nabil Iqbal & Syed Afraz Ali. No part of this publication may be reproduced, stored in a retrieval system, used in a spreadsheet, or transmitted in any form or by any means—electronic, mechanical, photocopying, recording, or otherwise—without the permission of the authors.

Grades	No. of Customers	No. of Defaults	Realized PDs	Bayesian Estimates	Implied PDs of Actual Portfolio	Implied PDs in Current Scenario
AAA	68	2	2.94%	4.76%	1.08%	0.80%
AA	112	2	1.79%	4.76%	1.74%	1.28%
А	238	6	2.52%	14.29%	2.33%	1.71%
BBB	514	4	0.78%	9.52%	2.55%	1.87%
BB	382	4	1.05%	9.52%	2.85%	2.08%
В	204	12	5.88%	28.57%	3.90%	2.83%
CCC	100	6	6.00%	14.29%	5.28%	3.81%
CC	68	2	2.94%	4.76%	6.36%	4.61%
С	24	4	16.67%	9.52%	10.46%	7.56%
Total	1,710	42				

Table 2.4

The above table illustrates that the implied probabilities of default under this scenario change compared to the implied probabilities of default of the actual portfolio. It is interesting to note that although, inputs in both scenarios were same, the probabilities of default have decreased. This proves the practicality and uniqueness of the model.

### 3.5. Scenario 4

In this scenario we observe the behavior of the model if the defaults occur only in the higher-level grades. Let's see the results first:

Grades	No. of Customers	No. of Defaults	Realized PDs	Bayesian Estimates	Implied PDs of Actual Portfolio	Implied PDs in Current Scenario
AAA	34	3	8.82%	8.57%	1.08%	1.92%
AA	56	7	10.71%	20.00%	1.74%	3.65%
А	119	9	5.88%	25.71%	2.33%	4.58%
BBB	257	2	0.78%	5.71%	2.55%	4.80%
BB	191	2	1.05%	5.71%	2.85%	5.09%
В	102	6	5.88%	17.14%	3.90%	6.08%
CCC	50	3	6.00%	8.57%	5.28%	7.42%
CC	34	1	2.94%	2.86%	6.36%	8.49%
С	12	2	16.67%	5.71%	10.46%	12.52%
Total	855	35				

Table 2.5

It's evident that as the number of defaults increase in the higher grades, the implied probabilities of default also increase and as per our model, it creates an impact on the lower grades as well; hence, the implied probabilities for lower grades. This behavior

Copyright © 2012 Nabil Iqbal & Syed Afraz Ali. No part of this publication may be reproduced, stored in a retrieval system, used in a spreadsheet, or transmitted in any form or by any means—electronic, mechanical, photocopying, recording, or otherwise—without the permission of the authors.

happens due to higher realized probabilities of default as well as the higher Bayesian estimates for the upper grades.

### 3.6. Scenario 5

We want to see the behavior if the number of defaults increase only in the lower grades. Definitely, by doing so, realized probabilities of default and the Bayesian estimates both will increase in the lower grades. Lets check the behavior of these changes on the whole portfolio:

Grades	No. of Customers	No. of Defaults	Realized PDs	Bayesian Estimates	Implied PDs of Actual Portfolio	Implied PDs in Current Scenario
AAA	34	1	2.94%	3.70%	1.08%	1.07%
AA	56	1	1.79%	3.70%	1.74%	1.73%
А	119	3	2.52%	11.11%	2.33%	2.31%
BBB	257	2	0.78%	7.41%	2.55%	2.53%
BB	191	2	1.05%	7.41%	2.85%	2.82%
В	102	6	5.88%	22.22%	3.90%	3.84%
CCC	50	6	12.00%	22.22%	5.28%	5.78%
CC	34	2	5.88%	7.41%	6.36%	7.35%
С	12	4	33.33%	14.81%	10.46%	12.59%
Total	855	27				

Table 2.6

This scenario produces some interesting results. The implied probabilities of default of the lower grades increased as expected but amazingly, the implied probabilities of default in the upper grades slightly decreased. This happens due the decreasing Bayesian estimates in the upper grades. If only realized probabilities of default are considered or only Bayesian estimates are considered then this dynamic nature of the model could not be observed.

## 3.7. Scenario 6

In this scenario, we will determine the impact on implied probabilities of default if only the customers in the middle grade i.e. from BBB to B default. The results are shown below:

Grades	No. of Customers	No. of Defaults	Realized PDs	Bayesian Estimates	Implied PDs of Actual Portfolio	Implied PDs in Current Scenario
AAA	34	1	2.94%	3.03%	1.08%	1.07%
AA	56	1	1.79%	3.03%	1.74%	1.72%
А	119	3	2.52%	9.09%	2.33%	2.30%
BBB	257	4	1.56%	12.12%	2.55%	2.62%
BB	191	7	3.66%	21.21%	2.85%	3.21%
В	102	11	10.78%	33.33%	3.90%	4.63%

Copyright © 2012 Nabil Iqbal & Syed Afraz Ali. No part of this publication may be reproduced, stored in a retrieval system, used in a spreadsheet, or transmitted in any form or by any means—electronic, mechanical, photocopying, recording, or otherwise—without the permission of the authors.

CCC 50   CC 34   C 12   Total 855		ble 2.7				
CC 34	33	Total				
	2	С	16.67%	6.06%	10.46%	11.06%
CCC 50	1	CC	2.94%	3.03%	6.36%	7.03%
	3	CCC	6.00%	9.09%	5.28%	5.97%

The realized probabilities of default as well as the Bayesian estimates of the middle grades increased. Due to this reason the lower grades i.e. from CCC to C received a negative impact and slightly increased. Actually, the decreasing Bayesian estimates in the lower grades is netting off the implied probabilities of default in these grades, thus the implied probabilities of default increased but not as much as in the middle grades. Higher grades showed interesting behavior too as the implied probabilities of default decreased with a minimal margin. This is because the activeness of defaults in these grades decreased due to the decreasing Bayesian estimates.

### 3.8. Scenario 7

In this scenario, we ignore the increase or decrease in the number of defaults. However, we will see the behavior of the portfolio if the number of customers increases instead. Therefore, we doubled the number of customers in the upper grade i.e. from AAA to A. Here are the results in the below table:

Grades	No. of Customers	No. of Defaults	Realized PDs	Bayesian Estimates	Implied PDs of Actual Portfolio	Implied PDs in Current Scenario
AAA	68	1	1.47%	4.76%	1.08%	0.55%
AA	112	1	0.89%	4.76%	1.74%	0.88%
А	238	3	1.26%	14.29%	2.33%	1.18%
BBB	257	2	0.78%	9.52%	2.55%	1.40%
BB	191	2	1.05%	9.52%	2.85%	1.70%
В	102	6	5.88%	28.57%	3.90%	2.75%
CCC	50	3	6.00%	14.29%	5.28%	4.13%
CC	34	1	2.94%	4.76%	6.36%	5.20%
С	12	2	16.67%	9.52%	10.46%	9.30%
Total	1,064	21				

Table 2.8

The results show that realized probabilities of default only decreased in the upper grades, while Bayesian estimates remained same in the whole portfolio. In this case the model is only taking the effect of decreasing realized probabilities of default in the upper grades while running the convolution mechanism. All other inputs are same for the process. In the end the implied probabilities of default show the decreasing behavior in the whole portfolio. It started with a major fall in the upper grades impacting middle and lower grades too.

#### 3.9. Scenario 8

Similarly, in this scenario we will increase the number of customers in the middle grades i.e. from BBB to B given that the number of defaults remain same. Results are given below:

Grades	No. of Customers	No. of Defaults	Realized PDs	Bayesian Estimates	Implied PDs of Actual Portfolio	Implied PDs in Current Scenario
AAA	34	1	2.94%	4.76%	1.08%	1.08%
AA	56	1	1.79%	4.76%	1.74%	1.74%
А	119	3	2.52%	14.29%	2.33%	2.33%
BBB	514	2	0.39%	9.52%	2.55%	2.44%
BB	382	2	0.52%	9.52%	2.85%	2.59%
В	204	6	2.94%	28.57%	3.90%	3.14%
CCC	50	3	6.00%	14.29%	5.28%	4.51%
CC	34	1	2.94%	4.76%	6.36%	5.59%
С	12	2	16.67%	9.52%	10.46%	9.69%
Total	1,405	21				

Table 2.9

Interestingly, implied probabilities of default of the middle grades decreased due to the decrement in the realized probabilities of default, while Bayesian estimates remained same for the entire portfolio. This is the main reason that the higher grades i.e. from AAA to A faced no impact in their implied probabilities of default. However, the implied probabilities of default of the lower grades decreased as per the mechanism of the model taking the decreasing effect from middle grades.

### 3.10. Scenario 9

Similarly as in Scenario 7 and 8, in the final Scenario, we increase the number of customers. However, this time we will observe the behavior of the model by showing the increase in the lower grades i.e. from CCC to C. Results are shown below:

Grades	No. of Customers	No of Defaults	Realized PDs	Bayesian Estimates	Implied PDs of Actual Portfolio	Implied PDs in Current Scenario
AAA	34	1	2.94%	4.76%	1.08%	1.08%
AA	56	1	1.79%	4.76%	1.74%	1.74%
А	119	3	2.52%	14.29%	2.33%	2.33%
BBB	257	2	0.78%	9.52%	2.55%	2.55%
BB	191	2	1.05%	9.52%	2.85%	2.85%
В	102	6	5.88%	28.57%	3.90%	3.90%
CCC	100	3	3.00%	14.29%	5.28%	4.61%

Total	951	21				
С	24	2	8.33%	9.52%	10.46%	7.36%
CC	68	1	1.47%	4.76%	6.36%	5.16%

**Table 2.10** 

We can see that the implied probabilities of default from the grades AAA to B remained unchanged from the actual portfolio. Bayesian estimates and realized probabilities of default both remained unchanged from the previous scenario. That is the reason that there was no change in that range. In contrast, the lower grades i.e. from CCC to C possess decreasing implied probabilities of default.

## 4. Open Issues

As this is a very new mechanism for calculating Probability of Default (PD), therefore there are few limitations which need to be discussed below. In our next version we will come up with further workings including overcoming these:

The first shortcoming is the decision to select the distributions. As per our decision, binomial and Poisson distributions were very sophisticated as per the portfolio and the mechanism. However, we can use other distributions as well. It should purely be the practitioner's choice.

The second shortcoming is the practice to cumulate the PDs of upper grades with the specific grade's PD. According to our mechanism, every grade should have a relation with the performance of other grade / grades. It means, if the PD of a better grade increases then it should impact its comparative lower grade in such a way that the PD / PDs for lower grade / grades are increased as well. However, in this case PD PDs of the higher grade / grades should remain same.

# 5. Conclusion

In this paper, we introduced a new model to estimate the Probability of Default (PD) for low defaults portfolio. The methodology is based on an actuarial mechanism named convolution. We calculated Bayesian Probability and Realized PD for each scenario by using these two estimates. We generated an implied distribution of each scenario by convolution technique. Besides that, we have developed different scenarios to see the behavior of the model. The model justified its performance very well. This model is very practical and related organizations can use this model accordingly.
